

Figure A1: **Distribution of baseline productive assets.** The figure shows the distribution of the constructed productive-asset measure prior to the log transformation. A substantial share of households have zero measured productive assets, while the positive portion of the distribution is strongly right-skewed.

Figure A2: **Cubic productive-asset transition functions by treatment group.** The fitted cubic relationships compare baseline and follow-up log productive assets for control, small-transfer, and large-transfer households. The dashed 45-degree line represents no change in productive assets between periods. The cubic specification does not reveal an unstable crossing with slope greater than one, supporting the qualitative conclusion of the main kernel-weighted specification.

**Table A1. Supplementary multivariate regression of follow-up productive assets.**  $R^2 = .085$  The dependent variable is log follow-up productive assets. Predictors include log baseline productive assets, indicators for small and large cash transfers, and interactions between baseline assets and each transfer condition. The regression is included as a supplementary comparison to the nonlinear transition-function analysis.
